

We all desire a more youthful appearance as we age. The harsh effects of the Australian sun can cause pigmentation, redness, lines and uneven texture. But more importantly it can cause skin cancer that may have a similar appearance.

It is vital that any new changes noticed on your skin should be checked by a doctor experienced in detecting skin cancer before undertaking any laser treatment. Whilst laser treatment improves the health and appearance of skin, it does not cure skin cancer.

Laser therapists and skin cancer nurses at Peninsula Skin Cancer Centre, Prue and Helena, stressed the importance of having your skin checked prior to any laser treatments.

“We have had patients who have booked to have some pigmentation removed by laser, only to find that it was melanoma and needed to be surgically removed before it became life threatening”.

“All patients are recommended to have their skin checked before laser treatment as we know how common skin cancer is. One in three Australians will have skin cancer by the age of seventy, and we’ve had over 120 melanomas at our clinic in 2015 already” said Helena. “It’s an epidemic”.

“Our clinic offers Cutera medical grade laser treatments to improve the general health and appearance of our patient’s skin. We treat sun damage, fine blood vessels, scars, redness and overall skin rejuvenation for healthy looking skin. This is all done as safely and effectively as possible under supervision of our trained and accredited doctors” Prue emphasised.

“Anyone interested in our laser treatment should book in for a Free consultation in our Frankston clinic”.
